10 **Summary**

11 In the present study, a sample of 88 animals belonging to four local (Modicana, Sarda, Sardo-Bruna
12 and Sardo-Modicana) and one cosmopolitan (Italian Brown Swiss) cattle breeds were genotyped with
13 a medium density SNP beadchip and compared in order to investigate their genetic diversity and the
14 existence of selection signatures. A total of 43,012 SNPs scattered across all twenty-nine autosomal
15 chromosomes were retained after the data quality control. Basic population statistics, Wright Fixation
16 Index and Runs of Homozygosity (ROH) analyses confirmed that Italian Brown genome was mainly
17 shaped by selection, as underlined by the low values of heterozygosity and minor allele frequency.
18 As expected, local cattle exhibited a large within breed genetic heterogeneity. The F_{ST} comparison
19 with the largest number of significant SNPs was Sardo-Bruna vs Sardo-Modicana, whereas the
20 smallest was observed for Italian Brown Swiss vs Sardo-Modicana, respectively. Modicana exhibited
21 the largest number of detected ROH, whereas the smallest was observed for Sardo-Modicana.
22 Signatures of selection were detected in genomic regions that harbor genes involved in milk
23 production traits for the Italian Brown Swiss and fitness traits for local breeds. According to the
24 results of Multi-Dimensional scaling and admixture analysis the Sardo-Bruna is more similar to the
25 Sarda rather than to the Italian Brown Swiss. Moreover, the Sardo-Modicana is genetically closer to

26 the Modicana rather than to the Sarda breed. Results of the present work confirm the usefulness of
27 Single Nucleotide Polymorphisms in deciphering the genetic architecture of livestock breeds.

28 **Keywords:** indigenous breeds, selection signatures, inbreeding, admixture, biodiversity

29

30 **Introduction**

31 The bovine domestication occurred presumably about 8-10 thousand years ago in southwest Asia
32 (Zeder 2017). This process led to the zebuine and taurine breeds (Loftus *et al.* 1994; Upadhyay *et al.*
33 2016) derived both from the extinct wild aurochs (*Bos primigenius*) that spread in Europe and Africa
34 in successive waves of migration. With domestication, cattle acquired a large variety of distinctive
35 traits compared to their wild ancestors: for example, they became smaller in size and developed the
36 capacity to adapt to various environments. During the Neolithic revolution, cattle accompanied
37 human migrations and crosses between individuals of different ethnic groups generated a gene flow
38 that changed the genetic makeup of their populations (Ajmone-Marsan *et al.* 2010).

39 The continuously increasing demand for work, milk and meat has enhanced between population
40 differences over the centuries. In particular, changes in the farming systems, intense implementation
41 of artificial selection, crossbreeding, and widespread use of artificial insemination that occurred in
42 the last decades resulted in a huge genetic improvement of few highly specialized cattle breeds.
43 However, as a consequence the within breed genetic variability has been seriously constrained in
44 these populations (Brotherstone and Goddard, 2005). Biodiversity has been drastically endangered,
45 a relevant reduction in the number of farmed cattle breeds has been observed leading to the
46 extinction of many local breeds. Indigenous populations, better suited to extensive farming but not
47 very productive, have been often abandoned in favor of highly productive breeds (Scherf 2000;
48 Medugorac *et al.* 2009).

49 Concerns about climate changes, ethical issues, and evolution of consumer needs, including
50 ecosystem services and landscape protection, are bringing towards sustainable livestock farming

51 systems. Such an evolving situation seems to offer new opportunities to indigenous breeds, because
52 of their strong linkage to the production area, large genetic variability, and great fitness. Local breeds,
53 are now considered as important reservoirs of resilience and biodiversity (Giovambattista *et al.* 2001).
54 Their genomes represent an ideal model for studying and understanding the evolutionary history of
55 livestock species, essential goal for evolutionary biology and population genetics. Moreover, local
56 breeds represent a source of income in marginal areas (Ruto *et al.* 2008) and a chance to answer to
57 the environmental changes (Medugorac *et al.* 2009). Their typical products support a sustainable
58 development of the rural environment and respond to new consumer demands for healthy foods.
59 In Italy there is a particular attention for biodiversity, due to the high number of native animal and
60 plant populations distributed throughout the whole country (Maiorano *et al.* 2007). Seventeen
61 indigenous cattle breeds have been officially recognized by the Italian Ministry of Agriculture. Of
62 particular interest is the situation of four cattle breeds farmed in extensive traditional systems in the
63 two main Italian Islands, Sicily and Sardinia. The Sarda (SAR) breed is present in the Island of
64 Sardinia since about 3,000 years BC. It originates from west Mediterranean cattle populations
65 (mainly from the Iberic peninsula) with influences from North African and Middle East breeds
66 (Della Maria 1936; Brandano *et al.* 1983a). At the end of the XIX century, crossbreeding with
67 Brown Swiss (BSW) bulls imported from Switzerland and Modicana (MOD) bulls imported from
68 Sicily were carried out in order to improve the aptitude of SAR to draught, milk and meat
69 production respectively. These crosses have led to the current Sardo-Bruna (SB) and Sardo-
70 Modicana (SM) breeds, respectively. The three Sardinian breeds have been officially recognized in
71 1985 with the establishment of the Herd book. The current population size, based on the number of
72 animals recorded in the Herd book, is 25,315 and 923 herds for the SAR, 2,822 and 150 herds for
73 the SM, and 33,662 and 1,426 herds for the SB respectively (www.aia.it).
74 The Modicana herdbook was established since 1952. Currently there are 5,209 animals recorded in
75 the herd book, farmed in 235 herds (www.aia.it). An early genetic characterization of these breeds

76 was carried out using morphologic measurements (Brandano *et al.*1983b), milk and blood protein
77 polymorphisms (Brandano *et al.* 1983c). Recently SM and MOD were compared in a study on coat
78 color genetic determinism using the *Melanocortin 1 receptor* gene (Guastella *et al.* 2011) and the
79 distribution of Runs of Homozygosity (ROH) was studied in MOD by Mastrangelo *et al.* (2016).
80 The SAR, MOD, and BSW can be considered as founder breeds and SB and SM are the derived
81 ones. In this work, a comparison between the five breeds is carried out using a medium density
82 (50K) SNP panel in order to investigate the genetic diversity and in particular to assess the extent of
83 diversity between pure-breeds and derived crosses. Moreover, gene discovery was performed in the
84 genomic regions that exhibited difference between breeds.

85

86 **Materials and methods**

87 **Animals and genotypic data**

88 A total of 88 animals of five different breeds were genotyped in outsourcing with the Illumina
89 BovineSNP50 beadchip: 22 BSW, 27 MOD, 19 SAR, 10 SB, and 12 SM, respectively. Genomic
90 DNA was obtained from blood samples for SB, MOD, SM, and from nasal swab for SAR, using the
91 NucleoSpin DNA rapidLyse Kit (Macherey-Nagel) according to manufacturer's instructions. For
92 BSW animals, genotype data were generated within the SELMOL research project using the
93 Genomix kit (Talent, Trieste, Italy). Animals of local breeds were randomly sampled from different
94 herds located in various areas of Sardinia and Sicily. Given the difficulty in gathering large samples
95 in local breeds, criteria used in the present work to include animals in the analysis were absence of
96 relatedness, distribution in the territory, morphological appearance and information based on farmer
97 interviews.

98 Since BSW animals were genotyped using Illumina BovineSNP50 v1 BeadChip in contrast to the
99 other genotypic data (Illumina BovineSNP50 v2), common markers were retained and remapped on
100 the UMD 3.1 release of the Bovine genome assembly. Only autosomal SNPs were considered.

101 Quality control was performed with Plink 1.9 (Purcell *et al.* 2007). Animals with a call rate > 95%
102 were retained. SNP selection was based on call rate (>97.5%), minor allele frequency (MAF>0.05),
103 and significant deviation for Hardy -Weimberg equilibrium ($P<0.00001$). After quality control,
104 43,012 common SNPs between the two Beadchip versions were retained. Missing genotypes were
105 imputed using Beagle 4 (Browning & Browning, 2016).

106

107 **Heterozygosity, Minor allele frequency and Linkage Disequilibrium**

108 Heterozygote count (HET) and the minor allele frequency (MAF) were calculated for each SNP
109 separately by breed using Plink 1.9. Linkage disequilibrium (LD) between markers was calculated
110 within 1000 kb distance (McKay *et al.* 2007) using Haploview (Barrett *et al.* 2005).

111

112 **Multi-dimensional scaling and admixture analysis**

113 The Multi-Dimensional scaling plot (MDS) and admixture analysis were performed using the
114 Zanardi pipeline (Marras *et al.* 2016) and “ggplot2” R package (Wickham, 2009). In MDS analysis,
115 a principal component (PC) analysis is performed on the genomic correlation matrix **G** and PC
116 scores are calculated for each individual. In order to confirm the animal classification in five
117 different breeds, the K parameter of admixture was fixed at 5.

118

119 **Wright Fixation Index and LOWESS**

120 Ten pair-wise comparisons were performed using the Wright fixation index (F_{ST}) calculated using
121 the equation proposed by Nei (1977):

$$122 \quad F_{ST} = (H_T - H_S) / H_T$$

123 where H_T is the observed total heterozygosity and H_S is the observed heterozygosity in each
124 population, respectively. For the F_{ST} calculation, an in house Python script was used. In order to
125 simplify the graphic interpretation of raw F_{ST} data, a Locally Weighted Scatterplot Smoothing

126 (LOWESS) procedure was used (Pintus *et al.* 2014). The LOWESS is a local smoothing regression
127 in which the space of the independent variable (in this case the progressive order of adjacent SNPs
128 along the chromosome) is fragmented into different intervals for which separate regressions are
129 fitted. The method is aimed at removing noise from raw data and at improving graphical
130 representation. A smoothing parameter corresponding to an interval of 20 SNPs for each local
131 regression was used.

132 A common problem when interpreting genetic difference metrics is the lack of proper statistical
133 tests. Some authors have proposed to fix a threshold based on the F_{st} distribution (Kijas *et al.* 2012;
134 Pintus *et al.*, 2014). Although the distribution of raw F_{st} values tends to be skewed, LOWESS
135 smoothed values could be considered approximately normally distributed. Thus, the significance
136 threshold in the present work was set to three standard deviation from the mean. Such a stringent
137 threshold was adopted considering the limited sample size.

138

139 **Runs of homozygosity**

140 Runs of Homozygosity (ROH) were detected using the Zanardi pipeline. Some constraints were
141 fixed in order to limit the number of spurious ROH segments (Marras *et al.* 2015): the minimum
142 length of ROH was set at 1 Mb, homozygous segments of minimum fifteen SNPs were considered
143 and neither heterozygous or missing genotypes were allowed. The following ROH statistics were
144 calculated by animal and by breed: number of ROH, the average ROH length (in Mb) and the sum
145 of all ROH segments by animal (S_{ROH} , in Mb). ROH were grouped into five classes of length ($1 < Mb$
146 ≤ 2 , $2 < Mb \leq 4$, $4 < Mb \leq 8$, $8 < Mb \leq 16$ and $Mb > 16$).

147 The ROH-based inbreeding coefficient (F_{ROH}) for each animal was calculated as

$$F_{ROH} = \frac{\sum S_{ROH(>8Mb)}}{L_{gen}}$$

148

149 where L_{gen} is the total length of genome. The minimum length of ROH to be included in the
150 calculation was fixed to 8 Mb based on previous reports in cattle (Marras *et al.* 2015). Moreover,
151 the ROH count per SNP (SNP_{ROH}), i.e. the number of animals having a given SNP included in a ROH
152 (Nothnagel *et al.* 2010) was calculated. A threshold of 50% was fixed to consider a SNP_{ROH} value as
153 significant.

154

155 **Gene discovery**

156 Gene discovery was performed in regions flagged by F_{ST} values exceeding the control chart upper
157 limit. Intervals spanning 0.25 Mb upstream and downstream the significant marker were
158 considered. Moreover, regions identified by ROH distribution were studied. In particular, markers
159 having $\text{SNP}_{\text{ROH}} > 50\%$ within a breed were considered as significant and the region spanning 0.25
160 Mb upstream and downstream surrounding them was investigated. Annotated genes were retrieved
161 from UCSC Genome Browser Gateway (<http://genome.ucsc.edu/>) and National Centre for
162 Biotechnology Information (NCBI) (www.ncbi.nlm.nih.gov) databases.

163

164 **Results**

165 HET and MAF showed a little variation between the five considered breeds (Table 1). BSW
166 showed smallest values of both HET and MAF, whereas MOD and SAR exhibited the largest
167 values for these parameters, respectively.

168 A clear distinction between the breeds could be observed along the first axis (PC1) of the MDS plot
169 (Fig. 1). In particular the PC1, that explains about 5.4% of the total variance, depicts a geographic
170 cline: starting from the bottom of the graph there are individuals from BSW (origin from the
171 Switzerland, North of Italy), then SAR and SB (centre of Italy), and at the top SM and MOD (native
172 of Sicily, Southern Italy). Furthermore, it could be seen that along this dimension, SM breed is
173 more similar to MOD than SAR. The second axis (PC2), explaining about 3% of the total variance,

174 highlights a separation within the SAR breed. The PC2 seemed to be able to discriminate animals
175 according to the percentage of SAR genetic contribution: an increase in PC2 scores indicates the
176 passage from SAR purebred to crosses, and then to MOD and BSW breeds. Population structure
177 analysed by admixture (Fig. 2) revealed a clear definition of BSW animals (95% assigned to a
178 single cluster, the one of red colour), and less precise for MOD and SAR (90% and 93% assigned to
179 two different clusters, respectively). Finally, also the derived breeds were grouped into two distinct
180 clusters (70% of both SB and SM cattle). The LD pattern (Fig. 3) shows the lowest value for MOD,
181 the highest for BSW and SB, respectively.

182 The F_{ST} comparison with the largest number of significant SNPs was SB vs SM, whereas the smallest
183 was observed for BSW vs SM (Table S1). Figure 4 reports Manhattan plots of F_{ST} predicted by
184 LOWESS for the comparisons between pure breeds and crosses. It can be observed that the highest
185 F_{ST} values between BSW and SB were found for BTA6 (Fig. 4a), with the top significant markers
186 (Table S2) located between 38.20 and 38.83 Mb. In this region map some known genes controlling
187 milk production traits (*ABCG2*, *PKD2*, *SPP1*, *LAP3*), and body size (*NCAPG* and *LCORL*) in cattle.
188 BTA8 and BTA13 showed the highest F_{ST} peaks in the SAR vs SB comparison (Fig. 4b) with seven
189 and three significant markers respectively (Table S2). In the region highlighted on BTA8 is located
190 the *microRNA2471* (*MIR2471*), whereas in the highlighted segment of BTA13 is annotated the
191 *Eukaryotic translation initiation factor 6* (*EIF6*) gene.

192 SAR and SM were different mainly on BTAs 7, 14, and 21 (Fig. 4c and Table S2). An interesting
193 gene retrieved from the database was the *Ubiquitin Protein Ligase E3A* (*UBE3A*) that maps in the
194 region between 2.1 and 2.3 Mb of BTA21.

195 As far as the comparison between SM and MOD is concerned (Fig. 4d), the highest values
196 of F_{ST} have been found on BTAs 5, 16 and 20 (Table S2). On BTA20 the region from 70.9 to 71.7
197 Mb presents a QTL associated with milk somatic cell score. Moreover, this segment contains

several annotated genes, among which of interest is the *Solute Carrier Family 9 Member A3* (SLC9A3).

Finally, for the SM vs SB comparison the highest values of F_{ST} have been detected on chromosomes 7 and 24 (Fig. 4e and Table S2). On BTA7, five significant markers define a region (47.2-47.3 Mbp) where the *Transcription Factor 7* (T-Cell Specific, HMG-Box) (TCF7) gene maps.

The total number of detected ROH (Table 2) exhibited a large variation between breeds, with MOD and SM having the largest and the smallest value, respectively. The BSW had the largest average ROH length, even if together with a huge variability as evidenced by the value of the standard deviation (Table 2). This breed had also the highest average number of SNP per ROH (Table 2). On the contrary MOD showed the smallest values of both statistics. As expected, most represented ROH classes in all breeds were those of length <4Mb (relative frequency ranging from 0.736 in BSW to 0.868 in MOD and SM, respectively). The largest number of ROH in the class of highest length (>16 Mb) was observed in BSW, and it was markedly larger than in all the other considered breeds (Table 2).

ROH count per SNP showed some interesting peaks along the genome. The highest peak was observed on BTA6 for BSW at approximately 30-40Mb (Fig. 5a). In this region map several known genes as *ABCG2*, *SPPI*, *LCORL*, *NCAPG*. BSW exhibited another signal between 10-30 Mb on BTA20 (Fig. 5b). Moreover, BTA1, BTA10 and BTA11 showed interesting signals of SNPs in homozygosity for over 50% of the animals. In particular, BSW showed a SNP_{ROH} peak on BTA1 (Fig. 6a) between 103.5 and 105.5 Mb. On the same chromosome, a peak was detected for MOD at 139.0 Mb. On BTA10 an interesting homozygous region was observed in the SAR breed between 72.2 and 72.8 Mb (Fig. 6b). Among the genes that map in this region the *Dehydrogenase/Reductase 7* (DHRS7) can be mentioned. Finally, the SB showed a relevant value of SNP_{ROH} on BTA11 (Fig. 6c) between 65.0 and 67.0 Mb where the *Ewing Tumor Associated Antigen 1* (ETAA1) was annotated.

223 BSW exhibited also the largest average F_{ROH} (Table 3) whereas the smallest value was observed by
224 SM.

225

226 Discussion

227 The practice of crossbreeding has represented a major cause of gene flow across cattle populations,
228 providing a relevant contribution to the shaping of worldwide current breeds. The history of the
229 Sarda breed and its crosses with Modicana and Brown Swiss represents a typical example. Results
230 of the present study confirm the genetic relationships between the considered breeds. The admixture
231 analysis (Fig. 2) clearly detected the five different genetic groups, highlighting the genetic
232 background of the crossbred derived population in comparison of the original purebreds.

233 Furthermore, the analyses of the genome features with different approaches gave useful insights on
234 effects of selection and environmental adaptation on the cattle genome.

235 A first indication was provided by basic population statistics. The lower genetic variability
236 exhibited by the BSW in comparison with the other two pure-breeds, SAR and MOD, was expected
237 due to the intense artificial selection this breed has been subjected to in the last decades
238 (www.anarb.it). A low allelic diversity for BSW cattle in comparison with other cattle breeds has
239 been already reported (Schmid *et al.* 1999; Melka & Schenkel 2012).

240 The genome feature analysis carried out using the MDS decomposition, and the ROH detection
241 highlighted an interesting structure of the considered sample of animals. The North-South
242 geographical gradient highlighted by the first axis of the MDS is in agreement with several studies
243 where a dimension reduction method is applied to molecular data on populations from different
244 geographical origin (Price 2006; Chessa *et al.* 2009; Ciani *et al.* 2014). Also, the variation of the
245 ROH statistics and of the inbreeding coefficient F_{ROH} exhibited the same cline. In particular the
246 average ROH length, the average number of SNP per ROH, and the F_{ROH} showed an increase moving
247 from South to North. This gradient was also confirmed by the LD analysis (Fig. 3). Purfield *et al.*

(2012) found a higher number of ROH in cattle breeds of British Isles compared to other European breeds and ascribed such a diversity to the closed population histories of these cattle. Results obtained in the present study can be probably due to a low effective population size of BSW and to the population history of the SAR, MOD, and their crosses. A geographical South-North gradient in ROH feature distribution has been observed also in human populations (Nothnagel *et al.* 2010), and it has been explained with the most pronounced genetic isolation of Northern populations compared to Mediterraneans. The second axis of the MDS analysis highlights two clusters in the sample of Sarda cattle (Fig. 1). Previous studies on this population highlighted a large morphological heterogeneity (Brandano *et al.* 1984). Moreover, in the traditional extensive cattle farming system of Sardinia it is not very common to exchange bulls between herds, resulting in a high average relatedness of individuals within farm and a low degree of kinship among farms. Different degree of genetic relationships between original and derived breeds have been observed. The similarity between SM and MOD was quite expected (Fig. 1). Although the first importation of MOD bulls from Sicily started at the end of the nineteenth century in the Montiferru area (Center-North Sardinia), it probably occurred again in more recent times and therefore the genetic component of Modicana purebred is still preserved into current SM. On the other hand, the separation between SB and the two founder breeds, i.e. BSW and SAR (Fig. 1), seems to indicate an absence of recent genetic exchange. The genetic history of the breeds is also depicted by other structural elements of their genome, as their linkage disequilibrium (Fig. 3) and the extent of regions of autozygosity (Fig. 5 and 6). The intensive genetic selection of BSW in comparison with the other investigated breeds resulted in the highest level of LD and in the largest values of all ROH statistics. These results agree with previous reports on this breed (Ferenčaković *et al.* 2013; Marras *et al.* 2015). A previous study on MOD breed reported a smaller value of F_{ROH} (Mastrangelo *et al.* 2016) but using different ROH settings (i.e. minimum number of SNP in a ROH equal to 40, minimum ROH length 4Mb, two missing SNP

273 allowed in a ROH etc.). An interesting result is the distribution across individuals of specific ROHs,
 274 i.e. a segment that starts and ends exactly in the same position. The largest ROH frequency was
 275 about 0.06 (Table 4) and it can be seen that in general local breeds tend to share ROH whereas the
 276 autozygous segment detected on BTA6 can be found only within the BSW breed. In particular, the
 277 latter ROH flagged a region where several known genes affecting milk traits are located. These
 278 results confirm the role of ROH as indicators not only of inbreeding but also of signatures of
 279 selection (Marras *et al.* 2014; Kim *et al.* 2015).
 280 Signatures of selection were highlighted in the present study. Some of them flagged genome regions
 281 already detected in many studies on cattle. An example is represented by the markers exhibiting the
 282 largest F_{ST} values in the BSW vs SB comparison, all located in the region of BTA6 spanning
 283 between 36-39Mb that harbors some known genes controlling milk production traits (*ABCG2*,
 284 *PKD2*, *SPP1*, *LAP3*) (Olsen *et al.* 2005; Cohen-Zinder *et al.* 2005) and body size (*NCAPG* and
 285 *LCORL*) (Takasuga 2016) (Table S2). This region was also flagged by a significant value of ROH
 286 count per SNP in BSW.
 287 Other two well known selection signatures were detected in BSW on BTA6 (Fig. 5a) by SNP_{ROH}
 288 significant values (>50%). The first was located at around 70 Mb, where the *V-Kit Hardy-*
 289 *Zuckerman 4 Feline Sarcoma Viral Oncogene Homolog (KIT)* locus maps. This gene is involved in
 290 mammalian coat colour determinism (Fontanesi *et al.* 2010; Stella *et al.* 2010). The second
 291 signature of selection, at around 85 Mb, identified the caseins cluster (Blott *et al.* 2003). Another
 292 interesting peak value of SNP_{ROH} was found on BTA20 (14-25 Mb) (Fig. 5b), in a region where a
 293 large QTL associated with milk protein percentage was reported (Ashwell *et al.* 2004) . Among the
 294 several genes that map in this region, of interest is the *Importin 11 (IPO11)* locus. This gene has
 295 been found to be associated with the displacement of the abomasum in German Holstein cattle
 296 breed (Mömke *et al.* 2013).

297 Interestingly, the F_{ST} pairwise comparison between the SAR and the SB did not detect SNPs located
 298 in genomic regions known to contain genes associated with milk production traits. These results,
 299 together with the pattern highlighted by the MDS, confirm that current SB is closer to SAR than to
 300 BSW, probably due to backcrossing.

301 Of interest are the signatures of selection found in the comparisons between local breeds. Some of
 302 them include interesting genes that were found to be associated with fitness traits. In the comparison
 303 between the SAR and its derived SB, the seven highly significant SNPs found on BTA8 between
 304 40.4 and 40.6 Mbp (Fig. 4b) identified a region where maps the *microRNA2471* (*MIR2471*). In
 305 animals, microRNAs are molecules involved in diverse biological processes such as development,
 306 cell differentiation, proliferation and metabolism. They are among major post-transcriptional
 307 regulators of gene expression through promoting mRNA degradation or translational repression
 308 (Glazov *et al.* 2009; Guo *et al.* 2010; Meunier *et al.* 2013). Recently they have been found to be
 309 essential for the regulation of the immune response (Xiao & Rajewsky 2009). The highest peak of
 310 F_{ST} comparison between the SAR and the other derived breed, the SM, was detected on BTA14 (Fig.
 311 4c and Table S2) in a region where maps the *gasdermin C* (*GSDMC*) locus. This gene was
 312 associated to UV-protective eye pigmentation in Fleckvieh cattle (Pusch *et al.* 2012). Another
 313 peak was located on BTA21, between 2.1 and 2.3 Mb, where the *Ubiquitin Protein Ligase E3A*
 314 (*UBE3A*) gene is annotated. This locus has been associated with the calving ease (Pausch *et al.*
 315 2011; Meszaros *et al.* 2016) in cattle. This trait represents very often a distinguishing feature in
 316 indigenous breed that are mainly reared in extensive and semi-extensive systems (Boggio *et al.*
 317 1988).

318 Other genes detected in the local breeds are related to milk production traits and fatty acid
 319 metabolism. Among genetic differences found between SM and MOD, of interest is the region
 320 located on BTA20, from 70.9 to 71.7 Mb. Among the annotated genes, is worth of mention the
 321 *Solute Carrier Family 9 Member A3* (*SLC9A3*), involved in the rumen sodium transport (Rabbani *et*

322 *al.* 2011). A high Na²⁺ tissue concentration improves milk production in warm/humid conditions
323 (Granzin & Gaughan 2002). Moreover, a QTL associated with milk somatic cell score was reported
324 in this region (Durán Aguilar *et al.* 2016). The comparison between the two derived breeds, i.e., SB
325 vs SM, found a selection signature defined by five significant markers (47.2-47.3 Mbp) on BTA7,
326 where maps the *Transcription Factor 7 (T-Cell Specific, HMG-Box) (TCF7)* gene. Recently, this
327 locus was associated with milk production in Chinese Holstein (Mao *et al.* 2015).
328 An interesting candidate gene highlighted by SNP_{ROH} in the SAR breed on BTA10 is the
329 *Dehydrogenase/Reductase 7 (DHR57)* locus. It catalyses the oxidation/reduction of a wide range of
330 substrates, including retinoid and steroids (Haeseleer & Palczewski 2000) and it has high expression
331 levels in adipocytes and skeletal muscles (Wu *et al.* 2009). In addition, this gene is responsible for
332 the final step in the cholesterol production (Porter 2000). This gene was already associated in
333 Nellore cattle with the intramuscular fat deposition and composition (Cesar *et al.* 2014). Finally,
334 another signature of selection that included a gene involved in fatty acid metabolism was found in
335 the SAR vs SB comparison (three significant markers on BTA13 between 65.1 and 65.2 Mb) (Fig.
336 4b). This region harbours the *Eukaryotic translation initiation factor 6 (EIF6)* locus. This gene
337 controls fatty acid synthesis and glycolysis in tissues responsive to insulin such as adipose and
338 muscular.

339

340 **Conclusion**

341 Results of the present work confirm the usefulness of genome structural features in deciphering the
342 genetic architecture of livestock breeds. The different approaches used to explore medium density
343 SNP genotypes gave a comprehensive picture of genetic relationships between the three original and
344 the two derived breeds, reflecting their recent genetic history. As expected, a larger heterogeneity was
345 highlighted for the local breeds. Signatures of selection located in genomic regions harboring
346 candidate genes for milk production traits have been detected in the comparisons involving the

347 specialized BSW breed, whereas for local breeds the flagged genes involved in fitness and fatty acid
348 metabolism. The study confirmed the importance of these populations as reservoir of biodiversity and
349 as models for studying the genetic basis of adaptability.

594 Modicana (MOD), Sarda (SAR), Sardo-Bruna (SB) and Sardo-Modicana (SM).

595 **Figure 2** Genetic structure and admixture plot obtained through coefficients of individual
596 membership to clusters (K=5) assumed to be present in the sample of investigated breeds. Red
597 columns = cluster 1; Light green columns = cluster 2; Blue columns = cluster 3; Green columns =
598 cluster 4; Purple columns = cluster 5.

599 **Figure 3** Average LD (r^2) between markers within an interval of 1000 kb in the five Italian cattle
600 breeds: Italian Brown Swiss (BSW), Modicana (MOD), Sarda (SAR), Sardo-Bruna (SB) and Sardo-
601 Modicana (SM).

602 **Figure 4** Manhattan plot of F_{ST} values predicted by the LOWESS. **a)** Comparison between Italian
603 Brown and Sardo-Bruna. **b)** Comparison between Sarda and Sardo-Bruna. **c)** Comparison between
604 Sarda and Sardo-Modicana. **d)** Comparison between Sardo-Modicana and Modicana. **e)** Comparison
605 between Sardo-Modicana and Sardo-Bruna. Red color dots indicate significant F_{ST} values (i.e. greater
606 than 3 standard deviations from the mean).

607 **Figure 5** Occurrence of SNP counted in a ROH measured by the percentage of animals belonging to
608 the five investigated breeds for which a particular SNP falls into a ROH versus the position along the
609 chromosome. **a)** Comparison of BTA6. **b)** Comparison of BTA20.

610 **Figure 6** Occurrence of SNP counted in a ROH measured by the percentage of animals belonging to
611 the five investigated breeds for which a particular SNP falls into a ROH versus the position along the
612 chromosome. **a)** Comparison of BTA1. **b)** Comparison of BTA10. **c)** Comparison of BTA11.
